Exercises

22.3-1
Do Exercise 22.2-2 using a disjoint-set forest with union by rank and path compression.

22.3-2
Write a nonrecursive version of FIND-SET with path compression.

22.3-3
Give a sequence of m MAKE-SET, UNION, and FIND-SET operations, n of which are MAKE-SET operations, that takes $\Omega(m \lg n)$ time when we use union by rank only.

22.3-4 ⋆
Show that any sequence of m MAKE-SET, FIND-SET, and UNION operations, where all the UNION operations appear before any of the FIND-SET operations, takes only $O(m)$ time if both path compression and union by rank are used. What happens in the same situation if only the path-compression heuristic is used?

⋆ 22.4 Analysis of union by rank with path compression

As noted in Section 22.3, the running time of the combined union-by-rank and path-compression heuristic is $O(m\,\alpha(m, n))$ for m disjoint-set operations on n elements. In this section, we shall examine the function α to see just how slowly it grows. Then, rather than presenting the very complex proof of the $O(m\,\alpha(m, n))$ running time, we shall offer a simpler proof of a slightly weaker upper bound on the running time: $O(m \lg^* n)$.

Ackermann's function and its inverse

To understand Ackermann's function and its inverse α, it helps to have a notation for repeated exponentiation. For an integer $i \geq 0$, the expression

$$2^{2^{\cdot^{\cdot^{\cdot^{2}}}}\}i}$$

stands for the function $g(i)$, defined recursively by

$$g(i) = \begin{cases} 2^1 & \text{if } i = 0\,, \\ 2^2 & \text{if } i = 1\,, \\ 2^{g(i-1)} & \text{if } i > 1\,. \end{cases}$$

Intuitively, the parameter i gives the "height of the stack of 2's" that make up the exponent. For example,

	$j = 1$	$j = 2$	$j = 3$	$j = 4$
$i = 1$	2^1	2^2	2^3	2^4
$i = 2$	2^2	2^{2^2}	$2^{2^{2^2}}$	$2^{2^{2^{2^2}}}$
$i = 3$	2^{2^2}	$2^{2^{\cdot^{\cdot^{\cdot^2}}}\}16}$	$2^{2^{\cdot^{\cdot^{\cdot^2}}}\}2^{2^{\cdot^{\cdot^{\cdot^2}}}\}16}}$	$2^{2^{\cdot^{\cdot^{\cdot^2}}}\}2^{2^{\cdot^{\cdot^{\cdot^2}}}\}2^{2^{\cdot^{\cdot^{\cdot^2}}}\}16}}}$

Figure 22.6 Values of $A(i, j)$ for small values of i and j.

$$2^{2^{\cdot^{\cdot^{\cdot^2}}}\}4} = 2^{2^{2^2}} = 2^{65536} .$$

Recall the definition of the function $\lg^*$ (page 36) in terms of the functions $\lg^{(i)}$ defined for integer $i \geq 0$:

$$\lg^{(i)} n = \begin{cases} n & \text{if } i = 0 , \\ \lg(\lg^{(i-1)} n) & \text{if } i > 0 \text{ and } \lg^{(i-1)} n > 0 , \\ \text{undefined} & \text{if } i > 0 \text{ and } \lg^{(i-1)} n \leq 0 \text{ or } \lg^{(i-1)} n \text{ is undefined} ; \end{cases}$$

$$\lg^* n = \min \left\{ i \geq 0 : \lg^{(i)} n \leq 1 \right\} .$$

The $\lg^*$ function is essentially the inverse of repeated exponentiation:

$$\lg^* 2^{2^{\cdot^{\cdot^{\cdot^2}}}\}n} = n + 1 .$$

We are now ready to show Ackermann's function, which is defined for integers $i, j \geq 1$ by

$$\begin{aligned} A(1, j) &= 2^j && \text{for } j \geq 1 , \\ A(i, 1) &= A(i - 1, 2) && \text{for } i \geq 2 , \\ A(i, j) &= A(i - 1, A(i, j - 1)) && \text{for } i, j \geq 2 . \end{aligned}$$

Figure 22.6 shows the value of the function for small values of i and j.

Figure 22.7 shows schematically why Ackermann's function has such explosive growth. The first row, exponential in the column number j, is already rapidly growing. The second row consists of the widely spaced subset of columns $2, 2^2, 2^{2^2}, 2^{2^{2^2}}, \ldots$ of the first row. Lines between adjacent rows indicate columns in the lower-numbered row that are in the subset included in the higher-numbered row. The third row consists of the even more widely spaced subset of columns $2, 2^{2^2}, 2^{2^{\cdot^{\cdot^{\cdot^2}}}\}16}, 2^{2^{\cdot^{\cdot^{\cdot^2}}}\}2^{2^{\cdot^{\cdot^{\cdot^2}}}\}16}}, \ldots$ of the second row, which is an even sparser subset of columns of the first row. In general, the spacing between columns of row $i - 1$ appearing in

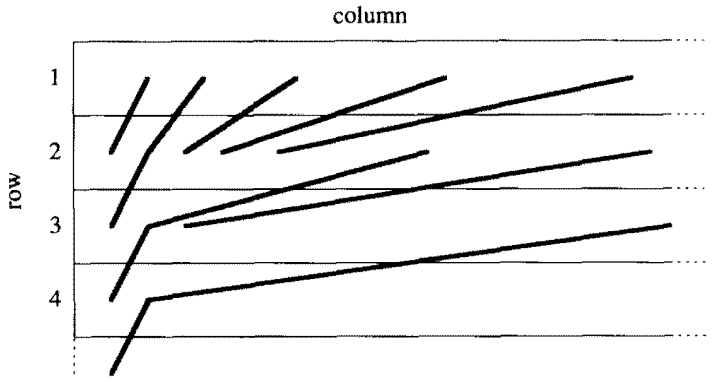

Figure 22.7 The explosive growth of Ackermann's function. Lines between rows $i-1$ and i indicate entries of row $i-1$ appearing in row i. Due to the explosive growth, the horizontal spacing is not to scale. The horizontal spacing between entries of row $i-1$ appearing in row i greatly increases with the column number and row number. If we trace the entries in row i to their original appearance in row 1, the explosive growth is even more evident.

row i increases dramatically with both the column number and the row number. Observe that $A(2,j) = 2^{2^{\cdot^{\cdot^{\cdot^{2}}}}\}j}$ for all integers $j \geq 1$. Thus, for $i > 2$, the function $A(i,j)$ grows even more quickly than $2^{2^{\cdot^{\cdot^{\cdot^{2}}}}\}j}$.

We define the inverse of Ackermann's function by[2]

$$\alpha(m,n) = \min\{i \geq 1 : A(i, \lfloor m/n \rfloor) > \lg n\} \ .$$

If we fix a value of n, then as m increases, the function $\alpha(m,n)$ is monotonically decreasing. To see this property, note that $\lfloor m/n \rfloor$ is monotonically increasing as m increases; therefore, since n is fixed, the smallest value of i needed to bring $A(i, \lfloor m/n \rfloor)$ above $\lg n$ is monotonically decreasing. This property corresponds to our intuition about disjoint-set forests with path compression: for a given number of distinct elements n, as the number of operations m increases, we would expect the average find-path length to decrease due to path compression. If we perform m operations in time $O(m\,\alpha(m,n))$, then the average time per operation is $O(\alpha(m,n))$, which is monotonically decreasing as m increases.

To back up our earlier claim that $\alpha(m,n) \leq 4$ for all practical purposes, we first note that the quantity $\lfloor m/n \rfloor$ is at least 1, since $m \geq n$. Since Ackermann's function is strictly increasing with each argument, $\lfloor m/n \rfloor \geq 1$ implies $A(i, \lfloor m/n \rfloor) \geq A(i,1)$ for all $i \geq 1$. In particular, $A(4, \lfloor m/n \rfloor) \geq$

[2]Although this function is not the inverse of Ackermann's function in the true mathematical sense, it captures the spirit of the inverse in its growth, which is as slow as Ackermann's function is fast. The reason we use the mysterious $\lg n$ threshold is revealed in the proof of the $O(m\,\alpha(m,n))$ running time, which is beyond the scope of this book.

$A(4,1)$. But we also have that

$$\begin{aligned} A(4,1) &= A(3,2) \\ &= 2^{2^{\cdot^{\cdot^{\cdot^{2}}}}\}16}, \end{aligned}$$

which is far greater than the estimated number of atoms in the observable universe (roughly 10^{80}). It is only for impractically large values of n that $A(4,1) \leq \lg n$, and thus $\alpha(m,n) \leq 4$ for all practical purposes. Note that the $O(m \lg^* n)$ bound is only slightly weaker than the $O(m\,\alpha(m,n))$ bound; $\lg^* 65536 = 4$ and $\lg^* 2^{65536} = 5$, so $\lg^* n \leq 5$ for all practical purposes.

Properties of ranks

In the remainder of this section, we prove an $O(m \lg^* n)$ bound on the running time of the disjoint-set operations with union by rank and path compression. In order to prove this bound, we first prove some simple properties of ranks.

Lemma 22.2
For all nodes x, we have $rank[x] \leq rank[p[x]]$, with strict inequality if $x \neq p[x]$. The value of $rank[x]$ is initially 0 and increases through time until $x \neq p[x]$; from then on, $rank[x]$ does not change. The value of $rank[p[x]]$ is a monotonically increasing function of time.

Proof The proof is a straightforward induction on the number of operations, using the implementations of MAKE-SET, UNION, and FIND-SET that appear in Section 22.3. We leave it as Exercise 22.4-1. ■

We define size(x) to be the number of nodes in the tree rooted at node x, including node x itself.

Lemma 22.3
For all tree roots x, size$(x) \geq 2^{rank[x]}$.

Proof The proof is by induction on the number of LINK operations. Note that FIND-SET operations change neither the rank of a tree root nor the size of its tree.

Basis: The lemma is true before the first LINK, since ranks are initially 0 and each tree contains at least one node.

Inductive step: Assume that the lemma holds before performing the operation LINK(x,y). Let *rank* denote the rank just before the LINK, and let *rank'* denote the rank just after the LINK. Define size and size' similarly.

If $rank[x] \neq rank[y]$, assume without loss of generality that $rank[x] < rank[y]$. Node y is the root of the tree formed by the LINK operation, and

$$\text{size}'(y) = \text{size}(x) + \text{size}(y)$$

$$\begin{aligned} &\geq 2^{rank[x]} + 2^{rank[y]} \\ &\geq 2^{rank[y]} \\ &= 2^{rank'[y]} . \end{aligned}$$

No ranks or sizes change for any nodes other than y.

If $rank[x] = rank[y]$, node y is again the root of the new tree, and

$$\begin{aligned} \text{size}'(y) &= \text{size}(x) + \text{size}(y) \\ &\geq 2^{rank[x]} + 2^{rank[y]} \\ &= 2^{rank[y]+1} \\ &= 2^{rank'[y]} . \end{aligned}$$

■

Lemma 22.4

For any integer $r \geq 0$, there are at most $n/2^r$ nodes of rank r.

Proof Fix a particular value of r. Suppose that when we assign a rank r to a node x (in line 2 of MAKE-SET or in line 5 of LINK), we attach a label x to each node in the tree rooted at x. By Lemma 22.3, at least 2^r nodes are labeled each time. Suppose that the root of the tree containing node x changes. Lemma 22.2 assures us that the rank of the new root (or, in fact, of any proper ancestor of x) is at least $r+1$. Since we assign labels only when a root is assigned a rank r, no node in this new tree will ever again be labeled. Thus, each node is labeled at most once, when its root is first assigned rank r. Since there are n nodes, there are at most n labeled nodes, with at least 2^r labels assigned for each node of rank r. If there were more than $n/2^r$ nodes of rank r, then more than $2^r \cdot (n/2^r) = n$ nodes would be labeled by a node of rank r, which is a contradiction. Therefore, at most $n/2^r$ nodes are ever assigned rank r. ■

Corollary 22.5

Every node has rank at most $\lfloor \lg n \rfloor$.

Proof If we let $r > \lg n$, then there are at most $n/2^r < 1$ nodes of rank r. Since ranks are natural numbers, the corollary follows. ■

Proving the time bound

We shall use the aggregate method of amortized analysis (see Section 18.1) to prove the $O(m \lg^* n)$ time bound. In performing the amortized analysis, it is convenient to assume that we invoke the LINK operation rather than the UNION operation. That is, since the parameters of the LINK procedure are pointers to two roots, we assume that the appropriate FIND-SET operations are performed if necessary. The following lemma shows that even

if we count the extra FIND-SET operations, the asymptotic running time remains unchanged.

Lemma 22.6
Suppose we convert a sequence S' of m' MAKE-SET, UNION, and FIND-SET operations into a sequence S of m MAKE-SET, LINK, and FIND-SET operations by turning each UNION into two FIND-SET operations followed by a LINK. Then, if sequence S runs in $O(m \lg^* n)$ time, sequence S' runs in $O(m' \lg^* n)$ time.

Proof Since each UNION operation in sequence S' is converted into three operations in S, we have $m' \leq m \leq 3m'$. Since $m = O(m')$, an $O(m \lg^* n)$ time bound for the converted sequence S implies an $O(m' \lg^* n)$ time bound for the original sequence S'. ■

In the remainder of this section, we shall assume that the initial sequence of m' MAKE-SET, UNION, and FIND-SET operations has been converted to a sequence of m MAKE-SET, LINK, and FIND-SET operations. We now prove an $O(m \lg^* n)$ time bound for the converted sequence and appeal to Lemma 22.6 to prove the $O(m' \lg^* n)$ running time of the original sequence of m' operations.

Theorem 22.7
A sequence of m MAKE-SET, LINK, and FIND-SET operations, n of which are MAKE-SET operations, can be performed on a disjoint-set forest with union by rank and path compression in worst-case time $O(m \lg^* n)$.

Proof We assess ***charges*** corresponding to the actual cost of each set operation and compute the total number of charges assessed once the entire sequence of set operations has been performed. This total then gives us the actual cost of all the set operations.

The charges assessed to the MAKE-SET and LINK operations are simple: one charge per operation. Since these operations each take $O(1)$ actual time, the charges assessed equal the actual costs of the operations.

Before discussing charges assessed to the FIND-SET operations, we partition node ranks into ***blocks*** by putting rank r into block $\lg^* r$ for $r = 0, 1, \ldots, \lfloor \lg n \rfloor$. (Recall that $\lfloor \lg n \rfloor$ is the maximum rank.) The highest-numbered block is therefore block $\lg^*(\lg n) = \lg^* n - 1$. For notational convenience, we define for integers $j \geq -1$,

$$B(j) = \begin{cases} -1 & \text{if } j = -1 , \\ 1 & \text{if } j = 0 , \\ 2 & \text{if } j = 1 , \\ 2^{2^{\cdot^{\cdot^{\cdot^{2}}}}\}j-1} & \text{if } j \geq 2 . \end{cases}$$

Then, for $j = 0, 1, \ldots, \lg^* n - 1$, the jth block consists of the set of ranks

$$\{B(j-1)+1, B(j-1)+2, \ldots, B(j)\} .$$

We use two types of charges for a FIND-SET operation: ***block charges*** and ***path charges***. Suppose that the FIND-SET starts at node x_0 and that the find path consists of nodes $x_0, x_1, \ldots, x_l$, where for $i = 1, 2, \ldots, l$, node x_i is $p[x_{i-1}]$ and x_l (a root) is $p[x_l]$. For $j = 0, 1, \ldots, \lg^* n - 1$, we assess one block charge to the *last* node with rank in block j on the path. (Note that Lemma 22.2 implies that on any find path, the nodes with ranks in a given block are consecutive.) We also assess one block charge to the child of the root, that is, to x_{l-1}. Because ranks strictly increase along any find path, an equivalent formulation assesses one block charge to each node x_i such that $p[x_i] = x_l$ (x_i is the root or its child) or $\lg^* rank[x_i] < \lg^* rank[x_{i+1}]$ (the block of x_i's rank differs from that of its parent). At each node on the find path for which we do not assess a block charge, we assess one path charge.

Once a node other than the root or its child is assessed block charges, it will never again be assessed path charges. To see why, observe that each time path compression occurs, the rank of a node x_i for which $p[x_i] \neq x_l$ remains the same, but the new parent of x_i has a rank strictly greater than that of x_i's old parent. The difference between the ranks of x_i and its parent is a monotonically increasing function of time. Thus, the difference between $\lg^* rank[p[x_i]]$ and $\lg^* rank[x_i]$ is also a monotonically increasing function of time. Once x_i and its parent have ranks in different blocks, they will always have ranks in different blocks, and so x_i will never again be assessed a path charge.

Since we have charged once for each node visited in each FIND-SET operation, the total number of charges assessed is the total number of nodes visited in all the FIND-SET operations; this total represents the actual cost of all the FIND-SET operations. We wish to show that this total is $O(m \lg^* n)$.

The number of block charges is easy to bound. There is at most one block charge assessed for each block number on the given find path, plus one block charge for the child of the root. Since block numbers range from 0 to $\lg^* n - 1$, there are at most $\lg^* n + 1$ block charges assessed for each FIND-SET operation. Thus, there are at most $m(\lg^* n + 1)$ block charges assessed over all FIND-SET operations.

Bounding the path charges is a little trickier. We start by observing that if a node x_i is assessed a path charge, then $p[x_i] \neq x_l$ before path compression, so that x_i will be assigned a new parent during path compression. Moreover, as we have observed, x_i's new parent has a higher rank than its old parent. Suppose that node x_i's rank is in block j. How many times can x_i be assigned a new parent, and thus assessed a path charge, before x_i is assigned a parent whose rank is in a different block (after which x_i will never again be assessed a path charge)? This number of times is maximized if x_i has the lowest rank in its block, namely $B(j-1)+1$, and its parents' ranks successively take on the values $B(j-1)+2, B(j-1)+3, \ldots, B(j)$.

Since there are $B(j) - B(j-1) - 1$ such ranks, we conclude that a vertex can be assessed at most $B(j) - B(j-1) - 1$ path charges while its rank is in block j.

Our next step in bounding the path charges is to bound the number of nodes that have ranks in block j for integers $j \geq 0$. (Recall that by Lemma 22.2, the rank of a node is fixed once it becomes a child of another node.) Let the number of nodes whose ranks are in block j be denoted by $N(j)$. Then, by Lemma 22.4,

$$N(j) \leq \sum_{r=B(j-1)+1}^{B(j)} \frac{n}{2^r} .$$

For $j = 0$, this sum evaluates to

$$\begin{aligned} N(0) &= n/2^0 + n/2^1 \\ &= 3n/2 \\ &= 3n/2B(0) . \end{aligned}$$

For $j \geq 1$, we have

$$\begin{aligned} N(j) &\leq \frac{n}{2^{B(j-1)+1}} \sum_{r=0}^{B(j)-(B(j-1)+1)} \frac{1}{2^r} \\ &< \frac{n}{2^{B(j-1)+1}} \sum_{r=0}^{\infty} \frac{1}{2^r} \\ &= \frac{n}{2^{B(j-1)}} \\ &= \frac{n}{B(j)} . \end{aligned}$$

Thus, $N(j) \leq 3n/2B(j)$ for all integers $j \geq 0$.

We finish bounding the path charges by summing over all blocks the product of the maximum number of nodes with ranks in the block and the maximum number of path charges per node of that block. Denoting by $P(n)$ the overall number of path charges, we have

$$\begin{aligned} P(n) &\leq \sum_{j=0}^{\lg^* n - 1} \frac{3n}{2B(j)} (B(j) - B(j-1) - 1) \\ &\leq \sum_{j=0}^{\lg^* n - 1} \frac{3n}{2B(j)} \cdot B(j) \\ &= \frac{3}{2} n \lg^* n . \end{aligned}$$

Thus, the total number of charges incurred by FIND-SET operations is $O(m(\lg^* n + 1) + n \lg^* n)$, which is $O(m \lg^* n)$ since $m \geq n$. Since there are $O(n)$ MAKE-SET and LINK operations, with one charge each, the total time is $O(m \lg^* n)$. ■

Corollary 22.8
A sequence of m MAKE-SET, UNION, and FIND-SET operations, n of which are MAKE-SET operations, can be performed on a disjoint-set forest with union by rank and path compression in worst-case time $O(m \lg^* n)$.

Proof Immediate from Theorem 22.7 and Lemma 22.6. ■

Exercises

22.4-1
Prove Lemma 22.2.

22.4-2
For each node x, how many bits are necessary to store size(x)? How about $rank[x]$?

22.4-3
Using Lemma 22.2 and Corollary 22.5, give a simple proof that operations on a disjoint-set forest with union by rank but without path compression run in $O(m \lg n)$ time.

22.4-4 ⋆
Suppose we modify the rule about assessing charges so that we assess one block charge to the last node on the find path whose rank is in block j for $j = 0, 1, \ldots, \lg^* n - 1$. Otherwise, we assess one path charge to the node. Thus, if a node is a child of the root and is not the last node of a block, it is assessed a path charge, not a block charge. Show that $\Omega(m)$ path charges could be assessed a given node while its rank is in a given block j.

Problems

22-1 Off-line minimum
The ***off-line minimum problem*** asks us to maintain a dynamic set T of elements from the domain $\{1, 2, \ldots, n\}$ under the operations INSERT and EXTRACT-MIN. We are given a sequence S of n INSERT and m EXTRACT-MIN calls, where each key in $\{1, 2, \ldots, n\}$ is inserted exactly once. We wish to determine which key is returned by each EXTRACT-MIN call. Specifically, we wish to fill in an array $extracted[1..m]$, where for $i = 1, 2, \ldots, m$, $extracted[i]$ is the key returned by the ith EXTRACT-MIN call. The problem is "off-line" in the sense that we are allowed to process the entire sequence S before determining any of the returned keys.
